## Majorana Fermions in a Superconductor

C. Chamon, R. Jackiw, Y. Nishida, S.Y. Pi, L. Santos

Model : Superconducting Proximity effect at the surface of a Topological Insulator

$$
\begin{aligned}
& \text { L. Fu and C. Kane (2008) } \\
& \text { R. Jackiw and P. Rossi (1981) }
\end{aligned}
$$

A Dirac type matrix equation governs surface excitations of a topological insulator in contact with an s-wave superconductor.

A vortex configuration in the superconductor leads to a static, isolated zero energy solution. Its mode function is real and has been called Majorana.

- will show that the Majorana feature is not confined to the zero energy mode, but characterizes the full quantum theory.
- will discuss the quantization procedure examining the Fock space realization of the zero mode algebra for the Dirac-type systems.

## Majorana Fermions

Central to recent research in
particle physics - neutrino physics, supersymmetry
cosmology - dark matter
condensed matter physics - exotic superconducting states
What is Majorana fermion ?
electrically charged particles - particle is different from its anti-particle which has opposite charge
electrically neutral particles - particle can be its own anti-particle
examples: neutral pions $(S=0)$, photons $(S=1)$, gravitons $(S=2)$
they are all bosons! - they are created by fields that obey
$\Phi=\Phi^{*}$ (reality condition)
fermions ( $S=\frac{1}{2}$ )
Dirac equation - complex numbers seem unavoidable successful theory for understanding spin and prediction of anti-matter

$$
\begin{aligned}
& \left(i \gamma^{\mu} \partial_{\mu}-\mathrm{m}\right) \Phi=0 \quad \Phi: \text { four-component spinor } \\
& \left\{\gamma^{\mu}, \gamma^{\nu}\right\}=2 \eta^{\mu \nu} \quad \text { (Clifford algebra) } \\
& \gamma^{0 \dagger}=\gamma^{0} ; \gamma^{i \dagger}=-\gamma^{i} \quad \text { (Hermitian Hamiltonian) }
\end{aligned}
$$

## Majorana's work (1937)

question: are equations for spin $\frac{1}{2}$ fields necessarily complex?
answer: there is a simple modification of Dirac equation that involve only real numbers.
$\Rightarrow$ profound implication that spin $\frac{1}{2}$ particles can be its own antiparticles!

Majorana field and its equation of motion

$$
\left(i \tilde{\gamma}^{\mu} \partial_{\mu}-m\right) \quad \Psi=0 \quad \Psi: \text { four-component spinor }
$$

$\tilde{\gamma}^{\mu}$ : purely imaginary, satisfying Clifford algebra
$\Rightarrow \quad \Psi$ can be real! $\Psi=\Psi^{*}$ reality condition
N.B. purely imaginary $\tilde{\gamma}^{\mu}$ : Majorana representation of $\gamma$-matrices

To describe Majorana fermions one does not need to use purely imaginary $\tilde{\gamma}^{\mu}$, but impose

$$
\Psi^{C} \equiv C \Psi^{*}=\Psi \quad \text { pseudo-reality condition }
$$

where $C$ is charge conjugation matrix.

$$
C=\left(\begin{array}{cc}
0 & -i \sigma^{2} \\
i \sigma^{2} & 0
\end{array}\right)
$$

Consider a four component spinor $\Phi=\binom{\psi}{\varphi}$
imposing $\quad C \Psi^{*}=\psi \quad \Rightarrow \quad \varphi=i \sigma^{2} \psi^{*} \quad\left(\psi=-i \sigma^{2} \varphi^{*}\right)$

$$
\psi=\binom{\psi}{i \sigma^{2} \psi^{*}} \quad \text { two component theory }
$$

Dirac:

$$
\begin{array}{cc} 
& \mathcal{L}_{D}=\bar{\Phi} i \gamma^{\mu} \partial_{\mu} \Phi-\frac{1}{2} \mathrm{~m} \bar{\Phi} \Phi \\
\Rightarrow \quad & \left(i \gamma^{\mu} \partial_{\mu}-\mathrm{m}\right) \Phi=0
\end{array}
$$

Majorana: imposing $\quad C \Psi^{*}=\Psi$

$$
\begin{gathered}
\mathcal{L}_{M}=\psi^{* T} i\left(\partial_{t}-\sigma \cdot \partial\right) \psi-\frac{1}{2} \mathrm{~m}\left(\psi^{* T} i \sigma^{2} \psi^{*}+h . c .\right) \\
\Rightarrow \quad i\left(\partial_{t}-\sigma \cdot \partial\right) \psi-\mathrm{m} i \sigma^{2} \psi^{*}=0
\end{gathered}
$$

N.B. Compare the mass terms:

Dirac: $\mathrm{m} \bar{\Phi} \Phi$ - preserves all quantum numbers
Majorana: m ( $\left.\psi^{* T} \sigma^{2} \psi^{*}+h . c.\right)$

- does not conserve any quantum numbers!
$\Rightarrow$ No distinction between particle and anti-particle since there are no conserved quantum numbers to tell them apart; particle is its own anti-particle

## Are there Majorana fermions in nature?

## neutrinos?

- recent development in neutrino physics
experimental observation of neutrino oscillations $\Rightarrow$
- neutrinos have mass ( $<0.1 \mathrm{eV}$ )
- lepton number is not conserved separately!
$\Rightarrow$ they could be Majorana fermions
Hypothetical Majorana fermions:
- supersymmetry - supersymmetric partners of photon, neutral Higgs boson, etc. are necessarily Majorana fermions
- cosmology - dark matter candidates

## Majorana fermions in superconductor in contact with a topological insulator

## Superconductor

$$
\text { proximity effects } \Rightarrow \text { Cooper pairs }
$$

tunnel through to the surface of TI
topological insulator

Hamiltonian density for the model:

$$
H=\psi^{* T}(i \sigma \cdot \partial-\mu) \psi+\frac{1}{2}\left(\triangle \psi^{* T} i \sigma^{2} \psi^{*}+h . c .\right)
$$

$\psi=\binom{\psi_{\uparrow}}{\psi_{\downarrow}}, \sigma=\left(\sigma^{1}, \sigma^{2}\right), \mu$ is chemical potential and $\triangle$ is the order parameter that may be constant or takes vortex profile, $\triangle(r)=v(r) e^{i \theta}$.

Equation of motion: $\quad i \partial_{t} \psi=(\sigma \cdot \partial-\mu) \psi+\triangle i \sigma^{2} \psi^{*}$
In the absence of $\mu$, and $\triangle$ constant, the above system is a ( $2+1$ )-dimensional version of (3+1)-dimensional, two component Majorana equation! - governs chargeless spin $\frac{1}{2}$ fermions with Majorana mass $|\triangle|$.

## Quantum Structure of the model / Quantization:

$\psi$ mixes with its complex conjugates in the equation of motion.
$\Rightarrow$ cannot construct energy eigenvalue problem
quantization is carried out both in particle physics and in superconductor by promoting the two component description to a constrained four component description:

$$
\psi=\left(\begin{array}{c}
\psi_{\uparrow} \\
\psi_{\downarrow} \\
\psi_{\downarrow}^{*} \\
-\psi_{\uparrow}^{*}
\end{array}\right)=\binom{\psi}{i \sigma^{2} \psi^{*}} .
$$

An extended Hamiltonian density $\mathcal{H}$ leads to equations for $\psi$, which are just two copies of $\mathcal{H}$ :

$$
\mathcal{H}=\frac{1}{2} \psi^{* T}\left(\begin{array}{ccc}
\sigma \cdot p-\mu & , & \triangle \\
\triangle^{*} & , & -\boldsymbol{\sigma} \cdot \boldsymbol{p}+\mu
\end{array}\right) \psi \equiv \frac{1}{2} \Psi^{* T} h \psi
$$

Bogoliubov-de Gennes equations for superconductor: Solve energy eigenvalue problem for unconstrained four component spinor $\Phi=\binom{\psi}{\varphi}$

$$
\begin{gathered}
h \Phi=i \partial_{t} \Phi, \Phi=e^{-i E t} \Phi_{E} \\
h \Phi_{E}=E \Phi_{E}
\end{gathered}
$$

$\Rightarrow$ construct Dirac field operator

$$
\begin{aligned}
\Phi & =\sum_{E>0} a_{E} e^{-i E t} \Phi_{E}+\sum_{E<0} b_{-E}^{\dagger} e^{-i E t} \Phi_{E} \\
& =\sum_{E>0}\left\{a_{E} e^{-i E t} \Phi_{E}+b_{E}^{\dagger} e^{i E t} C \Phi_{E}^{*}\right\}
\end{aligned}
$$

charge conjugation symmetry of $h$ has been used, $C \Phi_{+E}^{*}=\Phi_{-E}$

## Quantum field for superconductor:

$\bar{\Phi} \rightarrow \widehat{\psi}$ satisfying constraint $C \widehat{\Psi}^{\dagger}=\widehat{\Psi}$

$$
\widehat{\Psi}=\sum_{E>0}\left(a_{E} e^{-i E t} \Phi_{E}+a_{E}^{\dagger} e^{i E t} C \Phi_{E}^{*}\right)
$$

- $\widehat{\Psi}$ retains Majorana feature of describing excitations that carry no charge: current density for $\psi$ vanishes due to pseudo-reality constraint
N.B. The Majorana/reality properties are obscured by the representation of the Dirac matrices employed in presenting the Hamiltonian $h$. One may pass to the Majorana representation by a unitary transformation in which Hamiltonian is purely imaginary and $C=I$ so that pseudo reality condition becomes reality condition.

## Topological structure

Case of homogeneous order parameter:
energy eigenvalue $E= \pm \sqrt{(k \pm \mu)^{2}+m^{2}}$; no zero energy
( $\Delta e^{-i \omega}=m$; constant phase is removed and m is real constant of indefinite sign.)

At $\mu=0$ energy is doubly degenerate; degeneracy occurs because $h$ commutes with

$$
\begin{aligned}
S=\left(\begin{array}{cc}
0 & e^{i \omega} \sigma^{3} \\
e^{-i \omega} \sigma^{3} & 0
\end{array}\right) \Rightarrow & h^{\prime} \equiv S h=\Sigma_{a} n^{a} \\
& (a=1,2,3) \\
& n^{i}=k^{i}(i=1,2) \text { and } n^{3}=m
\end{aligned}
$$

A further unitary transformation shows that $\Sigma$ satisfies SU (2) algebra.

$$
U^{-1} \Sigma_{a} U=\left(\begin{array}{cc}
\sigma^{a} & 0 \\
0 & \sigma^{a}
\end{array}\right)
$$

Topological current in momentum space:

$$
\begin{aligned}
& K^{\mu}=\frac{1}{8 \pi} \varepsilon^{\mu \alpha \beta} \varepsilon_{a b c} \widehat{n}^{a} \partial_{\alpha} \hat{n}^{b} \partial_{\beta} \hat{n}^{c} \quad(\hat{n} \equiv \mathbf{n} /|\mathbf{n}|), \\
& \mathcal{N}=\int d^{2} k K^{0}(\mathbf{k})=\frac{1}{8 \pi} \int d^{2} k \frac{m}{\left(k^{2}+m^{2}\right)^{3 / 2}}=\frac{m}{2|m|}
\end{aligned}
$$

$\sim$ mapping of $R^{(2)}$ to $S^{(2)}: \hat{n}^{a}=(k \cos \varphi, k \sin \varphi, m) / \sqrt{k^{2}+m^{2}}$
When $k$ begins at $k=0, \hat{n}^{a}$ is at the north or south pole, as $k$ ranges to $\infty, \hat{n}^{a}$ covers a hemisphere (upper or lower) and ends at the equator of $S^{(2)}$. Thus only one half of $S^{(2)}$ is covered.

- evidence that the model belongs to a topologically non-trivial class.
$\Rightarrow$ topologically protected zero modes exist in the presence of a vortex.

## In the presence of a Single Vortex Order Parameter:

$$
\triangle(\mathbf{r})=v(r) e^{i \theta}
$$

Energy eigenvalue equation possesses an isolated zero energy mode:

$$
\begin{gathered}
\psi_{0}^{v}=N\binom{J_{0}(\mu r) \exp \{-i \pi / 4-V(r)\}}{J_{1}(\mu r) \exp \{i(\theta+\pi / 4)-V(r)\}} \begin{array}{l}
N: \text { real constant } \\
V^{\prime}(r)=v(r)
\end{array} \\
\Psi_{0}^{v}=\binom{\psi_{0}^{v}}{i \sigma^{2} \psi_{0}^{v *}} \quad C \Psi_{0}^{v *}=\Psi_{0}^{v}
\end{gathered}
$$

There are also continuum modes.

$$
\widehat{\Psi} \equiv \sum_{E>0}\left(a_{E} e^{-i E t} \Phi_{E}+a_{E}^{\dagger} e^{i E t} C \Phi_{E}^{*}\right)+A \sqrt{2} \Psi_{0}^{v}
$$

A is the operator for the zero mode and is Hermitian $A=A^{\dagger}$, anticommutes with ( $a_{E}, a_{E}^{\dagger}$ ) and obeys $\{A, A\}=2 A^{2}=1$.

## How is A realized on states ?

Two possibilities:

1) two one-dimensional realization : take the ground state to be an eigenstate of $A$; two eigenvalues $\pm \frac{1}{\sqrt{2}} \Rightarrow$ two ground states $\left|0_{+}\right\rangle$and $\left|0_{-}\right\rangle$

- Two towers of states built upon them; no local operator connects them.

$$
a_{E}^{\dagger} a_{E \prime}^{\dagger} a_{E \prime \prime}^{\dagger} \ldots|0 \pm\rangle
$$

- Fermion parity is lost since $A$ is a fermionic operator with

$$
\left\langle 0_{+}\right| A\left|0_{+}\right\rangle=\frac{1}{\sqrt{2}} \quad\left(\text { similarly for }\left|0_{-}\right\rangle\right)
$$

2) two-dimensional realization: vacuum is doubly degenerate - call one bosonic state $|b\rangle$, the other fermionic $|f\rangle$ and $A$ connects the two:

$$
A|b\rangle=\frac{1}{\sqrt{2}}|f\rangle \quad A|f\rangle=\frac{1}{\sqrt{2}}|b\rangle
$$

- two towers of states built on $|b\rangle$ and $|f\rangle$ are connected by $A$ !
observe: $\left|0_{+}\right\rangle=\frac{1}{\sqrt{2}}(|b\rangle+|f\rangle) \quad\left|0_{-}\right\rangle=\frac{1}{\sqrt{2}}(|b\rangle-|f\rangle)$
These states violate fermion parity.

## Which realization to choose?

To establish fermion parity preserving realization in the presence of a vortex we next consider vortex/anti-vortex background.

- There is no zero mid-gap mode - it splits into two low lying states with opposite energy; when vortex and anti-vortex are separated by a large distance $R, \varepsilon \approx \pm e^{-m R}$, where $m$ is the asymptotic value of $v(r)$ as $r \rightarrow \infty$.
- Quantum field

$$
\widehat{\Psi}=\widehat{\Psi}_{\text {cont }}+a_{\varepsilon} e^{-i \varepsilon t} \Psi_{\varepsilon}^{v \bar{v}}+a_{\varepsilon}^{\dagger} e^{i \varepsilon t} C \Psi_{\varepsilon}^{v \bar{v}}
$$

Fock space spectrm
low-lying state:

$$
\begin{array}{lr}
a_{\varepsilon}|\Omega\rangle=0 & a_{\varepsilon}^{\dagger}|\Omega\rangle=|f\rangle \\
a_{\varepsilon}|f\rangle=|\Omega\rangle & a_{\varepsilon}^{\dagger}|f\rangle=0
\end{array}
$$

Remaining states:

$$
\begin{aligned}
& a_{E}^{\dagger} a_{E^{\prime}}^{\dagger} \cdots|\Omega\rangle \\
& a_{E}^{\dagger} a_{E^{\prime}}^{\dagger} \cdots|f\rangle
\end{aligned}
$$

Limit $R \rightarrow \infty: \psi \psi_{ \pm \varepsilon \hat{v}}^{\varepsilon \rightarrow 0} \psi_{0}^{v}$

$$
\begin{gathered}
\begin{array}{c}
\widehat{\Psi}=\widehat{\Psi}_{\text {cont }}+\frac{\left(a_{\varepsilon}+a_{\varepsilon}^{\dagger}\right)}{\sqrt{2}} \sqrt{2} \psi_{0}^{v} \\
= \\
\begin{cases}A=A^{\dagger} & \{A, A\}=1 \\
|\Omega\rangle \equiv|b\rangle\end{cases} \\
\Rightarrow A|b\rangle=\frac{1}{\sqrt{2}}|f\rangle
\end{array} \quad A|f\rangle=\frac{1}{\sqrt{2}}|b\rangle
\end{gathered}
$$

Note:
Above discussion is somewhat qualitative since no explicit solutions are available in the background of vortex/anti-vortex. However, in 1-d, with Majorana fermions in the presence of kink/anti-kink background, one may solve equations explicitly and verify above statement. [See G. W. Semenoff and P. Sodano (2006) - these authors do not definitely select between the one- and two-dimensional representations of the zero mode algebra.]

Remaining Question : Who will discover Majorana fermions first, condensed matter physicists or particle physicists ?
